an answer to this question. The answer is unambiguous and is generally agreed upon by all scientists who have considered all the evidence. This evidence strongly supports the conclusion that genetic factors are much more important than environmental influences in accounting for individual differences in I.Q. How much more important? The evidence indicates that genetic factors account for at least twice as much of the variation in I.Q.'s as environmental factors. This conclusion has one main limitation. Since all of the major studies in this field were conducted with samples of Caucasian European and North American populations, we cannot confidently generalize their conclusions to other populations, especially those with very dissimilar environments.

What are the kinds of evidence that lead to the conclusion that genetic differences outweigh environmental differences in accounting for individual differences in I.Q.? Most of this evidence, as it is found in the scientific literature, depends upon quite technical methods of analysis developed in a specialty known as quantitative genetics or population genetics. Some of these methods were devised originally to analyze the roles of heredity and environment in agriculture and animal breeding.

Experiments in Animal Breeding

Experiments in which we explicitly try to breed for some specific trait give us the most certain evidence that variation in the trait has a genetic component. Psychologists have bred rats for speed of learning mazes, which is a good indicator of rat intelligence. By always mating the fast-learning males with fast-learning females, and mating slowlearning males with slow-learning females, it is possible, within 6 to 10 generations, to produce two quite distinct strains of rats in respect to mazelearning ability. The slowest-learning rat of the "bright" strain will learn mazes faster than the fastest rat of the "dull" strain. The two strains will differ markedly in the number of tries they need to learn how to run through a maze efficiently, avoiding the blind alleys. These experiments definitely prove that not only physical characteristics but some behavioral traits as well are largely inherited through the parental genes. Thus we should not be surprised to find in humans that differences in some behavioral characteristics, including intelligence, are a product of genetic inheritance. **Identical Twins Reared Apart**

One of the most important lines of evidence for the inheritance of intelligence in humans comes from studies of identical twins who were separated shortly after birth and reared in different homes. Identical twins originate from a single fertilized ovum which splits in the course of early development to form two individuals. Each member of the pair of twins therefore has exactly the same complement of genes. Consequently, any difference between the twins must be due entirely to nongenetic or environmental differences.

Twins separated shortly after birth are often reared in families that differ markedly in social class, and the range of environmental differences observed in their foster homes is fairly typical of the environmental variations seen in the general population.

Four major studies of identical twins reared apart, conducted in England, Denmark, and the United States, and totaling 122 pairs of twins, are in remarkably close agreement in showing that twins reared in different homes are still much more

Do I.Q. Tests Measure Intelligence? DAVID C. McCLELLAND

Psychology has one great practical success to its credit in the twentieth century-namely the intelligence testing movement. Many tests have been devised which predict success in school with remarkable regularity. Literally tens of thousands of validity coefficients have been calculated, demonstrating that those who score higher on aptitude or intelligence tests usually do better in their school work. Selecting, at random, a finding which is quite typical for the United States, I recently observed in a longitudinal study to be reported by Costa (1972) that Kuhlman-Anderson I.Q. scores obtained in the sixth grade correlated 0.59 with twelfth-grade rank in class. In other words knowing how a child scores on an intelligence test when he is eleven or twelve years old enables you to predict fairly accurately how well he will be doing in school some six or seven years later. Rank in class at graduation from secondary school in turn predicts whether he can go on to the university and how good a university he will get into. As a con-

David C. McClelland is Professor of Psychology, Harvard University. Appointed to Harvard in 1956, he has also served as chairman of the Fulbright Advisory Panel on Psychology and as director of research projects for the Ford Foundation, the Carnegie Foundation, the State Department, the National Institute of Mental Health and the Peace Corps. Professor McClelland is author of many books, including Personality; The Achieving Society; The Roots of Consciousness; Motivating Economic Achievement, and Alcohol and Human Motivation.

sequence, knowing a person's intelligence-test score or scholastic-aptitude-test score has become a matter of great importance in the United States, not only to admissions officers who use it to pick people for college but also to businesses and civil service commissions who use it to decide who is "bright enough" to be a policeman, a social worker or a fireman.

Testing has therefore become big business. The Educational Testing Service which gives the Scholastic Aptitude Test used by most of the better-known colleges and universities in the United States employs around two thousand people and has a large plant spread over hundreds of acres in Princeton, New Jersey. Thousands of young people pay to take its tests annually to see if they are qualified to get into the college of their choice. The testing technology has been so sold to the American public that only in a few of the more "backward" parts of the society is it not used in the schools or businesses or civil service. And of course it is spreading fast to the rest of the world, which is beginning to discover the utility of tests for picking those who will do well in school.

To be sure, the testers themselves loudly insist

that there are other important human qualities besides the ability to take scholastic aptitude tests, but as Wing and Wallach (1971) have shown, admissions officers may believe they take these other qualities into account but in fact their selection decisions can be almost perfectly predicted by aptitude-test scores alone. The desire to select more "intelligent" people for schooling or for almost any occupation proves overpowering. It quickly reduces other qualifications to insignificance.

While the intelligence-testing movement in the United States has been moving on from one triumph to the next, some questions have been raised about its theoretical underpinnings, both by scholars and by policy makers who wonder if its growing power over people's lives is justified. One difficulty with tests has long been known but little commented on perhaps because its seriousness has not been fully appreciated. It is very simply that if academic achievement tests are taken seriously as measures of real competence, then the quality of education does not seem to contribute to improving competence. Back in the 1930's in the United

States, a number of private schools tried to improve the quality of their education as part of what was then known as the "progressive education movement." Standardized scholastic achievement tests were used to evaluate the effects of this supposedly improved education as compared with more traditional teaching.

By and large no effects of the supposedly higher-quality education could be discovered in the test scores. The educators felt they were doing a better job but the test scores did not indicate that they were. The same finding has turned up again and again since that time. Certain colleges in the United States are widely acknowledged to be better than other colleges-in the sense that they have better faculties, more books in the library, higher endowments, better laboratory facilities, and so forth. Yet repeated studies as summarized by Jacob (1957) have failed to show any test-score differences attributable to the better education supposedly obtained in the elite colleges. If the graduates of those colleges perform better on achievement tests, it is because they scored higher on them at entrance to college, not because they received a better education subsequently.

Most recently in a very important social document on equality of educational opportunity, Coleman (1966) again showed that the quality of education (here in secondary school) seemed to have very little effect on the academic achievement test scores of children. In other words the children who went to poor schools with poorly trained teachers, dilapidated buildings, and crowded classrooms did no worse on the tests than children who went to excellent, well-equipped schools with low teacher-pupil ratios, once one had corrected for the initial differences in intelligence and social background of the pupils attending the two types of schools. In other words what the test results seem to have shown over and over again is that quality of education makes no difference in improving competence.

What does make a difference are the attributes of the people getting the education—their intelligence, their social characteristics and so forth. Why then should citizens spend so much money trying to improve education? Why should educational psychologists be trying to find better ways of educating pupils? Why is money wasted on conferences to try to find ways of improving education—if in fact the data clearly show that educational variations have very little effect on academic achievement, which in turn is considered the main measure of competence for life's tasks?

One reason is that we keep suspecting that the educators may be right in continuing to think that the quality of education does make a difference. It may be the psychological testers who are wrong: their tests may simply not be adequate measures of the competence which better education produces. In fact there may even be a built-in theoretical reason why most existing tests are inadequate measures of variations in the quality of education. Most testers have worked hard to create tests which are reliable-that is, which will give the same score when the same individual is tested again. An instrument which is designed to be very reliable may not be very sensitive to changes that have actually taken place in the person through education

But this theoretical problem has never shaken the self-confidence of the testing movement. It has continued to roll on like a juggernaut overwhelming all such doubts.

When many psychologists began to examine really seriously for the first time the assumptions on which the intelligence testing movement had been built, it took them no time at all to discover that many intelligence tests had a built-in middleclass bias. The vocabulary used in the tests was so-called "standard English," not the dialect spoken in many ghetto communities. So the children from these communities often did not even understand the instructions for the tests, let alone the words they were supposed to identify which were not part of the vocabulary in common use in their community. Correct answers to questions also often assume a standard middle-class way of life. For example a child is asked on an intelligence test, "What would you do if you were sent to the store by your mother to buy something and you found the store didn't have it?" The "intelligent" or correct answer is supposed to be that you would go to another store to see if they had it. However this is certainly not an intelligent answer for a ghetto child who is under strict orders from his mother to come straight home from the store because she is afraid he might be robbed or beaten if he strayed Continued on page 152

Comments on Individual and Group Differences in I.Q. SANDRA SCARR-SALAPATEK

Thanks to Jensen's provocative article, many academic psychologists who thought I.Q. tests belonged in the closet with the Rorschach inkblots have now explored the psychometric literature and found it to be a trove of scientific treasure. One of these is Richard Herrnstein, who from a Skinnerian background [B.F. Skinner, Professor of Psychology, Harvard University] has become an admirer of intelligence tests—a considerable leap from shaping the behavior of pigeons and rats. Herrnstein's popular account in the *Atlantic* of I.Q. testing and its values is generally responsible, if overly enthusiastic in parts.

Herrnstein unabashedly espouses I.Q. testing as "psychology's most telling accomplishment to date," despite the current controversy over the fairness of testing poor and minority-group children with I.Q. items devised by middle-class whites. His historical review of I.Q. test development, including tests of general intelligence and multiple abilities, is interesting and accurate. His

account of the validity and usefulness of the tests centers on the fairly accurate prediction that can be made from I.Q. scores about academic and occupational achievement and income level. He clarifies the pattern of relationship between I.Q. and these criterion variables: High I.Q. is a necessary but not sufficient condition for high achievement, while low I.Q. virtually assures failure at high academic and occupational levels. One must assume that Herrnstein's enthusiasm for intelligence tests rests on population statistics, not on predictions for a particular child, because many children studied longitudinally have been shown to change I.Q. scores by twenty points or more from childhood to adulthood. It is likely that extremes of giftedness and retardation can be sorted out relatively early by I.Q. tests, but what about the 95 percent of the population in between? Their I.Q. scores may vary from dull to bright normal for many years. Important variations in I.Q. can occur up to late adolescence. On a population basis Herrnstein is correct; the best early predictors of later achievement are ability measures taken from age five on. Predictions are based on correlations,

however, which are not sensitive to absolute changes in value, only to rank orders. This is an important point to be discussed later.

After reviewing the evidence for average I.Q. differences by social class and race, Herrnstein poses the nature-nurture problem of "which is primary?" in determining phenotypic differences in I.Q. For racial groups, he explains, the origins of mean I.Q. differences are indeterminate at the present time because we have no information from heritability studies in the black population or from other, unspecified, lines of research which could favor primarily genetic or primarily environmental hypotheses. He is thoroughly convinced, however, that individual differences and social-class differences in I.Q. are highly heritable at the present time and are destined, by environmental improvements, to become even more so.

For Herrnstein, society is, and will be even more strongly, a meritocracy based largely on inherited differences in I.Q.

Five "corollaries" for the future predict that the heritability of I.Q. will rise; that social mobility will become more strongly related to inherited

Sandra Scarr-Salapatek is an Associate Professor in the Institute of Child Development, University of Minnesota. Her research on genetic and environmental factors in personality and intellectual development has been published in many scientific journals. She is a Harvard Ph. D. in child development and behavioral genetics. Dr. Scarr-Salapatek has an unusual name because she is married to Dr. Philip Salapatek, also at the Institute of Child Development. Thanks to an excellent housekeeper, the household, which includes three children and numerous pets, runs pretty smoothly. The children all show individual differences.

I.Q. differences; that most bright people will be gathered in the top of the social structure, with the I.Q. dregs at the bottom; that many at the bottom will not have the intelligence needed for new jobs; and that the meritocracy will be built not just on inherited intelligence but on all inherited traits affecting success, which will presumably become correlated characters. Thus, from the successful realization of our most precious egalitarian political and social goals, there will arise a much more rigidly stratified society, a "virtual caste system" based on inborn ability.

To ameliorate this effect, society may have to move toward the socialist dictum, "From each according to his abilities, to each according to his needs," but Herrnstein sees complete equality of earnings and prestige as impossible because highgrade intelligence is scarce and must be recruited into those critical jobs that require it, by the promise of high earnings and high prestige. Although garbage collecting is critical to the health of the society, almost anyone can do it; to waste high-I.Q. persons on such jobs is to misallocate scarce resources at society's peril. the educational implications of the wide range of apparent differences in educability in our population.

There is fundamentally, in my opinion, no difference, psychologically and genetically, between individual differences and group differences. Individual differences often simply get tabulated so as to show up group differences-between as schools in different neighborhoods, between different racial groups, between cities and regions. They then become a political and ideological. not just a psychological, matter. To reduce the social tensions that arise therefrom, we see proposals to abolish aptitude and achievement testing, grading, grade placement, special classes for the educationally retarded and the academically gifted, neighborhood schools, the classroom as the instructional unit, the academic curriculum, and even our whole system of education. There may be merit in some of these proposals. But I think they are too often aimed at covering up problems rather than coming to grips with them.

Greater Attention to Learning Readiness. The concept of developmental readiness for various kinds of school learning has been too neglected in recent educational trends, which have been dominated by the unproved notion that the earlier something can be taught to a child, the better. Forced early learning, prior to some satisfactory level of readiness (which will differ markedly from one child to another), could cause learning blocks which later on practically defy remediation. The more or less uniform lockstep sequencing of educational experiences may have to be drastically modified for the benefit of many children, but the recent massive insistence on "earliness" and equality of educational treatment of all children has militated against large-scale research on the implications of readiness for children with below-average educability within the traditional school system.

Greater Diversity of Curricula and Goals. Public schools, which aim to serve the entire population, must move beyond narrow conceptions of scholastic achievement to find a greater diversity of ways for children over the entire range of abilities to benefit from their schooling-to benefit especially in ways that will be to their advantage when they are out of school. The academic goals of schooling are so ingrained in our thinking and our values that it will probably call for radical efforts to modify public education in ways such that it will maximally benefit large numbers of children with very limited aptitude for academic achievement. I believe that a wellintentioned but misconceived social egalitarian ideology has prevented public education in the United States from facing up to this challenge.

The belief that equality of edu-

cational opportunity should necessarily lead to equality of performance, I believe, is proving to be a false hope. It is the responsibility of scientific research in genetics, psychology, and education to determine the basis for realistic solutions to the problems of universal public education. Though it may be premature to prescribe at present, I venture the prediction that future solutions will take the form not so much of attempting to minimize differences in scholastic aptitudes and motivation, but of creating a greater diversity of curricula, instructional methods, and educational goals and values that will make it possible for children ranging over a wider spectrum of abilities and proclivities genuinely to benefit from their years in school. The current Zeitgeist of environmentalist equalitarianism has all but completely stifled our thinking along these lines. And I believe the magnitude and urgency of the problem are such as to call for quite radical thinking if the educational eliminate human differences. Rather than making over a large segment of the school population so they will not be doomed to failure in a largely antiquated, elitist-oriented, educational system which originally evolved to serve only a relatively small segment of society, the educational system will have to be revamped in order to benefit everyone who is required by the society to attend school. It seems incredible that a system can still survive which virtually guarantees frustration and failure for a large proportion of the children it should intend to serve.

But we should not fail to recognize that to propose radical diversity in accord with individual differences in abilities and interests, as contrasted with uniformity of educational treatment, puts society between Scylla and Charybdis in terms of insuring for all individuals equality of opportunity for the diversity of educational paths. The surest way to maximize the benefits of schooling to all individuals and at the same

system is truly to serve the whole of society. We have invested so much for so long in trying to equalize scholastic performance that we have given little or no thought to finding ways of diversifying schools to make them rewarding to everyone while not attempting to equalize everyone's performance in a common curriculum. Recommendations have almost always taken the form of asking what next we might try to make children who in the present school system do not flourish academically become more like those who do. The emphasis has been more on changing children than on revamping the system. A philosophy of equalization, however laudable its ideals, cannot work if it is based on false premises, and no amount of propaganda can make it appear to work. Its failures will be forced upon everyone. Educational pluralism of some sort, encompassing a variety of very different educational curricula and goals, I think, will be the inevitable outcome of the growing realization that the schools are not going to time to make the most of a society's human resources is to insure equality of educational opportunity for all its members. Monolithic educational goals and uniformity of approaches guarantee unnecessary frustration and defeat for many. On the other hand, educational pluralism runs the risk that social, economic, ethnic background or geographic origin, rather than each child's own characteristics, might determine the educational paths available to him. The individual characteristics appropriate for any one of a variety of educational paths and goals are to be found everywhere, in every social stratum, ethnic group, and neighborhood. Academic aptitudes and special talents should be cultivated wherever they are found, and a wise society will take all possible measures to insure this to the greatest possible extent. At the same time, those who are poor in the traditional academic aptitudes cannot be left by the wayside. Suitable means and goals must be found for making their years of schooling rewarding to

them, if not in the usual academic sense, then in ways that can better their chances for socially useful and self-fulfilling roles as adults. Ξ

California Institute of Technology Engineering and Science magazine, Pasadena, California, April, 1970.

1.Q. MCCLELLAND continued from page 14

too far from familiar territory. Yet if he says he would go home he is judged by the testers to be less intelligent. It is also easy to see from these examples why there is a correlation between test performance and later performance in school because the teacher, as a representative of standard middle-class culture, will expect the same language and types of behavior as the person who made up the so-called intelligence test. The teacher will either not understand the dialect that is used in class or will give the child a lower mark for using "bad" language and the ghetto child will before long go through life stigmatized as being less intelligent and a poor student.

Looking at the problem this way forced psychologists to consider seriously another possible explanation for many of the existing correlations between intelligence test scores, doing well in school, and holding down higher-status jobs later in life. Those who control not only economic and social opportunities but also what language and values are the standards by which others will be judged, may in fact be able to use test scores to maintain their power. All one needs to assume is that more powerful families are in a much better position to help their children get higher-status jobs: they know the right people; they can send their children to the right schools; they can use their influence to get them jobs directly. So it turns out that people in higher-status jobs score higher on so-called intelligence tests.

But where is the direct evidence that the higher score on the test in fact indicated that the person was better able to do the higher-status job? As every psychologist knows, correlation does not mean causation. It doesn't follow that because professionals score higher than laborers on certain tests that it is the ability to perform those particular tests which enabled them to be professionals rather than laborers. The reason why people have assumed that causation was involved is that the test scores were supposed to indicate how intelligent the person was, and it seems reasonable to assume that being a professional requires more of something called intelligence than being a laborer does. However it is by no means as selfevident as it once was that these test scores measure the kind of intelligence implied by the logic of this Continued on page 154

argument. They may simply indicate that the person has the *credentials* that the power elite insists that he must have in order to hold a higherstatus job. The connection between test performance and job performance may well be extrinsic rather than intrinsic. That is, being able to use the right words may have nothing to do intrinsically with whether a person is a cleverer lawyer, but those in power in a society simply decree that a person cannot be a lawyer unless he uses the correct vocabulary. In this sense the test becomes an instrument for those in power to screen out those who do not know the right words and who are therefore "unqualified" to be lawyers in the minds of those who control such things. Now such a selection procedure may be justifiable in one way or another but it does serve to make clear that the central issue is who is in power and controlling resources, not who is genetically inferior in intelligence.

American psychologists have long accepted without question Professor Terman's conclusion (1947) that his gifted children (those with higher intelligence test scores) grew up to be more successful occupationally, maritally, and socially than those of average intelligence and that they showed fewer "morally deviant" forms of psychopathology such as alcoholism or homosexuality. Yet the power analysis just carried out suggests that neither Professor Terman nor anyone else has as yet brought forward conclusive evidence that it is giftedness per se as he measured it that is responsible for these happier life outcomes. For his gifted children were also drawn very disproportionately from the ranks of the educated, the wealthy, and the powerful. This means that they had not only a better chance to acquire the characteristics measured in the test but also to be happier (since they had more money) and also to have access to higher occupations and better social standing. Maybe test scores measuring "giftedness" are simply another symptom of their generally more favorable social status. Copyright David C. McClelland, 1972.

CUSTOM MADE BRIDE

come out to his house right away." "What bank does he use?" I said.

"He doesn't use a bank," said Hal. "He uses a wicker basket under his drafting table. Get out there and get that basket."

Otto's home and place of business is thirty miles from town, in a wilderness by a waterfall. It looks, roughly, like a matchbox resting on a spool. The upper story, the matchbox, has glass walls all the way around, and the lower story, the spool, is a windowless brick cylinder.

There were four other cars in the guest parking area when I arrived for the first time. A small cocktail party was in progress. As I was skirting the house, wondering how to get into it, there came a tapping on a glass wall above. I looked up to see the most startling, and, in a bizarre way, one of the most beautiful women of my experience.

She was tall and slender, with a subtly muscled figure sheathed in zebra-striped leotards. Her hair was bleached silver and touched with blue, and, in the white and perfect oval of her face were eyes of glittering green, set off by painted eyebrows, jet-black and arched. She wore one earring, a barbaric gold hoop. She was making spiral motions with her hand, and I understood at last that I was to climb the spiral ramp that wound around the brick cylinder.

The ramp brought me up to a catwalk outside the glass walls. A towering, vigorous man in his early thirties slid back a glass panel and invited me in. He wore lavender nylon coveralls and sandals. He was nervous, and there was tiredness in his deep-set eyes.

"Mr. Krummbein?" I said.

"Who else would I be?" said Otto. "And you must be the wizard of high finance. We can go into my studio, where we'll have more privacy, and then you can join us in a drink."

His studio was inside the brick cylinder, and he led me through a door and down another spiral ramp into it. There were no windows. All the light was artificial.

"Guess this is the most modern house I've ever been in," I said.

"Modern?" said Otto. "It's twenty years behind the times, but it's the best my imagination can do. Everything else is at least a hundred years behind the times, and that is why we have all the unrest, this running to psychiatrists, broken homes, wars. We haven't learned to design our living for our own times. Our lives clash with our times. Look at your clothes! Shades of 1910. "Did you ever see a woman who fitted so well into surroundings like this—who seems herself to be designed for contemporary living?" said Otto. "A rare thing, believe me. I've had many famous beauties out here, but Falloleen is the only one who doesn't look like a piece of 1920-vintage overstuffed furniture

"... And, of course, you just don't even go near a potato!"

You're not dressed for 1954."

"Maybe not," I said humbly, "but I'm dressed for selling securities."

"You are being suffocated by tradition," said Otto. "Why don't you say, 'I am going to build a life for myself, for my time, and make it a work of art?? Your life isn't a work of art—it's a third-hand Victorian whatnot shelf, complete with someone else's collection of seashells and hand-carved elephants."

"Yup," I said, sitting down on a twenty-foot couch. "That's my life, all right."

"Design your life like that Finnish carafe over there," said Otto, "clean, harmonious, alive with the cool, tart passion of reason in our time. Like Falloleen."

"I'll try," I said gamely. "Mostly, it's a question of getting my head above water first. What is Falloleen, a new miracle fiber?"

"My wife," said Otto. "You no doubt noticed her-the one in the leotards."

"Indeed I did," I said.

in this house."

"How long have you been married?" I said.

"The party upstairs is in celebration of one month of blissful marriage," said Otto; "of a honeymoon that will never end."

"How nice," I said. "And now, about your financial picture--"

Otto looked at me uneasily. "Just promise me one thing," he said, "don't be depressing. I can't work if I'm depressed. The slightest thing can throw me off-that tie of yours, for instance. It jars me. I can't think straight when I look at it. Would you mind taking it off? Lemon yellow is your color, not that dismal maroon."

Half an hour later, tieless, I felt like a man prowling through a city dump surrounded by smoldering tire casings, rusting bedsprings and heaps of tin cans, for that was the financial picture of Otto Krummbein. He kept no books, bought whatever caught his fancy, without considering the cost, owed ruinous bills all over town for clothes for Falloleen, and didn't have one cent in a savings account, insurance or a portfolio.

"Look," said Otto, "I'm scared; I don't want to go to prison; I didn't mean to do anything wrong; I've learned my lesson." He took a Bible from a shelf and laid his hand on it."I hereby swear to do anything you say, absolutely anything! Just don't depress me."

"If you can be cheerful about this mess," I said, "the Lord knows I can. The thing to do, I think, is to save you from yourself by letting me manage your income, putting you on an allowance."

"Excellent," said Otto. "I admire a bold approach to problems. And that will leave me free to work out an idea I got on my honeymoon, an idea that is going to make millions. I'll wipe out all this indebtedness in one fell swoop!"

"Just remember," I said, "you're going to have to pay taxes on that too. You're the first man I ever heard of who got a profitable idea on his honeymoon. Is it a secret?"

"Moonlight-engineered cosmetics," said Otto, "designed expressly, according to the laws of light and color, to make a woman look her best in the moonlight. Millions, zillions!"

"That's swell," I said, "but, in the meantime, I'd like to go over your bills to see exactly how deep in you are, and also to figure out what allowance you could get by on at a bare minimum."

"You could go out to supper with us tonight," said Otto, "and then come back and work undisturbed here in the studio. I'm sorry we have to go out, but it's the cook's day off."

"That would suit me fine," I said. "That way I'll have you around to answer questions. There ought to be plenty of those. For instance, how much is in the basket?"

Otto paled. "Oh, you know about the basket?" he said. "I'm afraid we can't use that. That's special."

"In what way?" I said.

"I need it-not for me, for Falloleen," said Otto. "Can't I keep that much, and send you all the royalty checks that come in from now on? It isn't right to make Falloleen suffer because of my mistakes. Don't force Copyright of Saturday Evening Post is the property of Benjamin Franklin Literary & Medical Society.
